

Talk your architecture into existence.

A voice-controlled architecture canvas. Describe a system out loud; it draws, validates, and stress-tests itself in place.

Systems are designed in conversation. Diagrams are drawn afterwards, by hand, and nobody checks them.

The whiteboard photo

Design reviews end with a blurry photo and a promise to “clean it up later”. The decision record never gets written.

Diagram tools are slower than talking

Dragging boxes breaks the flow of a design discussion, so the diagram lags the conversation or gets skipped.

Text-to-diagram draws anything

One-shot generators happily connect a browser to a database. They don't know the rules, so they don't push back.

Failure modes surface in production

Single points of failure and synchronous chains are obvious in hindsight, and invisible on a static diagram.

Say it. Watch it build, break, and heal.

How it uses the AssemblyAI Voice Agent API

One socket, no exposed keys

The server mints a single-use token; the browser opens one WebSocket, streams 24 kHz PCM, and ends every session with `session.end`.

9 general tools, strict schemas

Add, connect, insert, update, remove, simulate, review, canvas. Enums come from the catalog, and every call is validated locally before it touches the graph.

Edits land instantly, results wait their turn

Each `tool.call` applies immediately; `tool.result` is held until `reply.done` is the latest event, so turn-taking never breaks.

The agent always sees the canvas

After every edit, `session.update` pushes the live graph into `system_prompt` and refreshes keyterms with your own component names.

Barge-in and voice undo

Speech flushes playback mid-word. “Undo that” and “redo” are just tools.

Measured, not vibes

What makes it different

Edits in place, not regenerate

Every utterance is a small, typed, undoable edit to the existing diagram, with animation that shows exactly what changed.

A rules engine with a voice

Illegal connections are rejected and explained out loud with a fix. Inferred choices are badged, explained, and one tap to undo.

Architecture you can crash

Traffic simulation and chaos mode turn a static picture into a model: overloads, cascading failure, failover, and remedies.

Artifacts from the typed graph

Terraform, Mermaid, and ADR exports are generated from the same model, so they can't drift from the picture.

Business

Who pays

Engineering teams that run design reviews, and solutions-engineering teams that draw customer architectures on calls.

How it spreads

Diagrams leave the tool as Mermaid in PRs and ADRs in repos, each one a link back. Free solo tier, paid team workspaces.

Pricing

Solo free. Team \$18 per editor per month with unlimited voice and shared history. Enterprise with SSO and bring-your-own LLM through AssemblyAI.

Unit economics

Voice minutes are the main cost and scale with usage; typed editing, linting, simulation, and exports run entirely in the browser.

Built to keep

Typed domain core

A headless engine: 42 catalog components, legality rules, inference, deterministic layout, linter, simulation, remedies. No React, fully unit-tested.

One path for every input

Voice, typed commands, drag and drop, and one-tap fixes all compile to the same validated commands, so behavior is identical everywhere.

Storage behind an interface

Local by default; set two environment variables and diagrams and version history move to Redis. Share links encode the graph.

Product name in one constant

Rename, re-voice, or re-greet the product by editing a single config file.

What's next

Multiplayer rooms

Several voices, one canvas, with speaker-aware edits during a live design review.

Import what exists

Read Terraform, Kubernetes manifests, or a cloud account to start from the real system.

Cost and latency estimates

Attach price and p99 models to the catalog and simulate them alongside load.

Dial in to the canvas

AssemblyAI's SIP support lets someone describe an incident from a phone while the team watches it draw.

Say the first component.
